Classification

Email: Spam / Not Spam?

Online Transactions: Fraudulent (Yes / No)?

Tumor: Malignant / Benign?

 $y \in \{0, 1\}$ 0: "Negative Class" (e.g., benign tumor)

1: "Positive Class" (e.g., malignant tumor)

Threshold classifier output $h_{\theta}(x)$ at 0.5:

If
$$h_{\theta}(x) \geq 0.5$$
, predict "y = 1"

If $h_{\theta}(x) < 0.5$, predict "y = 0"

Classification: y = 0 or 1

$$h_{\theta}(x)$$
 can be > 1 or < 0

Logistic Regression: $0 \le h_{\theta}(x) \le 1$

Hypothesis Representation

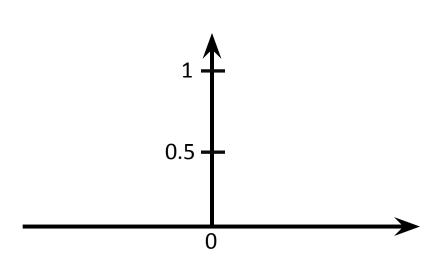

(How the function will look like?)

Logistic Regression Model

Want $0 \le h_{\theta}(x) \le 1$

$$h_{\theta}(x) = \theta^T x$$

Sigmoid function Logistic function

Interpretation of Hypothesis Output

 $h_{\theta}(x)$ = estimated probability that y = 1 on input x

Example: If
$$x = \begin{bmatrix} x_0 \\ x_1 \end{bmatrix} = \begin{bmatrix} 1 \\ \text{tumorSize} \end{bmatrix}$$

$$h_{\theta}(x) = 0.7$$

Tell patient that 70% chance of tumor being malignant

"probability that y = 1, given x, parameterized by
$$\theta$$
"
$$P(y=0|x;\theta)+P(y=1|x;\theta)=1$$

$$P(y=0|x;\theta)=1-P(y=1|x;\theta)$$

Decision Boundary

(Talking about the decision boundary will give us a better sense of what the logistic regression hypothesis function is computing.)

$$h_{\theta}(x) = g(\theta^T x)$$
$$g(z) = \frac{1}{1 + e^{-z}}$$

Suppose predict "y = 1" if $h_{\theta}(x) \ge 0.5$

predict "
$$y = 0$$
" if $h_{\theta}(x) < 0.5$

Let's use this to better understand how the hypothesis of logistic regression makes those predictions.

Decision Boundary

$$h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$$

Predict "y = 1" if $-3 + x_1 + x_2 \ge 0$

Non-linear decision boundaries

So with these visualizations, I hope that gives you a what's the range of hypothesis functions we can represent using the representation that we have

Now that we know what h(x) can represent.

Next: see how to automatically choose the parameters theta.

So that given a training set we can automatically fit the parameters to our data.

Cost Function

Training set: $\{(x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \dots, (x^{(m)}, y^{(m)})\}$

$$\in \left[\begin{array}{c} x_1 \\ \dots \end{array}\right]$$

m examples
$$x \in \begin{bmatrix} x_0 \\ x_1 \\ \cdots \\ x_n \end{bmatrix}$$
 $x_0 = 1, y \in \{0, 1\}$

$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}}$$

How to choose parameters θ ?

Cost function

Linear regression: $J(\theta) = \frac{1}{m} \sum_{i=1}^{m} \frac{1}{2} \left(h_{\theta}(x^{(i)}) - y^{(i)} \right)^2$

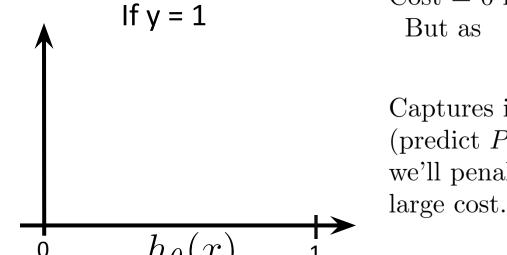

$$\operatorname{Cost}(h_{\theta}(x^{(i)}), y^{(i)}) = \frac{1}{2} \left(h_{\theta}(x^{(i)}) - y^{(i)} \right)^{2}$$
"non-convex"
$$J(\theta)$$

$$\theta$$

$$J(\theta)$$

Logistic regression cost function

$$Cost(h_{\theta}(x), y) = \begin{cases} -\log(h_{\theta}(x)) & \text{if } y = 1\\ -\log(1 - h_{\theta}(x)) & \text{if } y = 0 \end{cases}$$

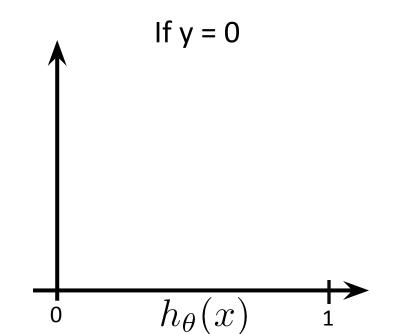

$$Cost = 0 \text{ if } y = 1, h_{\theta}(x) = 1$$

But as $h_{\theta}(x) \to 0$ $Cost \to \infty$ Captures intuition that if $h_{\theta}(x) = 0$, (predict $P(y = 1 | x; \theta) = 0$), but y = 1, we'll penalize learning algorithm by a very large cost.

Logistic regression cost function

$$Cost(h_{\theta}(x), y) = \begin{cases} -\log(h_{\theta}(x)) & \text{if } y = 1\\ -\log(1 - h_{\theta}(x)) & \text{if } y = 0 \end{cases}$$

Cost Function and Gradient Descent

Logistic regression cost function

$$J(\theta) = \frac{1}{m} \sum_{i=1}^{m} \operatorname{Cost}(h_{\theta}(x^{(i)}), y^{(i)})$$

$$Cost(h_{\theta}(x), y) = \begin{cases} -\log(h_{\theta}(x)) & \text{if } y = 1\\ -\log(1 - h_{\theta}(x)) & \text{if } y = 0 \end{cases}$$

Note: y = 0 or 1 always

Logistic regression cost function

$$J(\theta) = \frac{1}{m} \sum_{i=1}^{m} \text{Cost}(h_{\theta}(x^{(i)}), y^{(i)})$$

To fit parameters θ :

$$\min_{\theta} J(\theta)$$

To make a prediction given new x:

Output
$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}}$$

Gradient Descent

```
Want \min_{\theta} J(\theta): Repeat \{ \theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta) \{ (simultaneously update all \theta_j)
```

Gradient Descent

```
Want \min_{\theta} J(\theta): Repeat \{ \theta_j := \theta_j - \alpha \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)} (simultaneously update all \theta_j)
```

Algorithm looks identical to linear regression!

Multi-class Classification One-vs-All

Binary classification:

Multi-class classification:

One-vs-all (one-vs-rest):

One-vs-all

Train a logistic regression classifier $h_{\theta}^{(i)}(x)$ for each class i to predict the probability that y=i.

On a new input x, to make a prediction, pick the class i that maximizes

$$\max_{i} h_{\theta}^{(i)}(x)$$
